# Forms in Web Applications - Tasks

- Initialize Default Values
- Validate Data
- Display Validation messages

The image shows a web form titled "Angular Connect ID". It contains a text input field with the placeholder text "Connect ID". Below the input field, there is a red validation message: "Please enter ID in the pattern AA-XX where A is letter and X is a number". The form is enclosed in a black border.

# Angular 2 – Types of Forms

**Template Driven Forms**

**Model Driven  
(Reactive Forms)**

# Angular 2 – Types of Forms

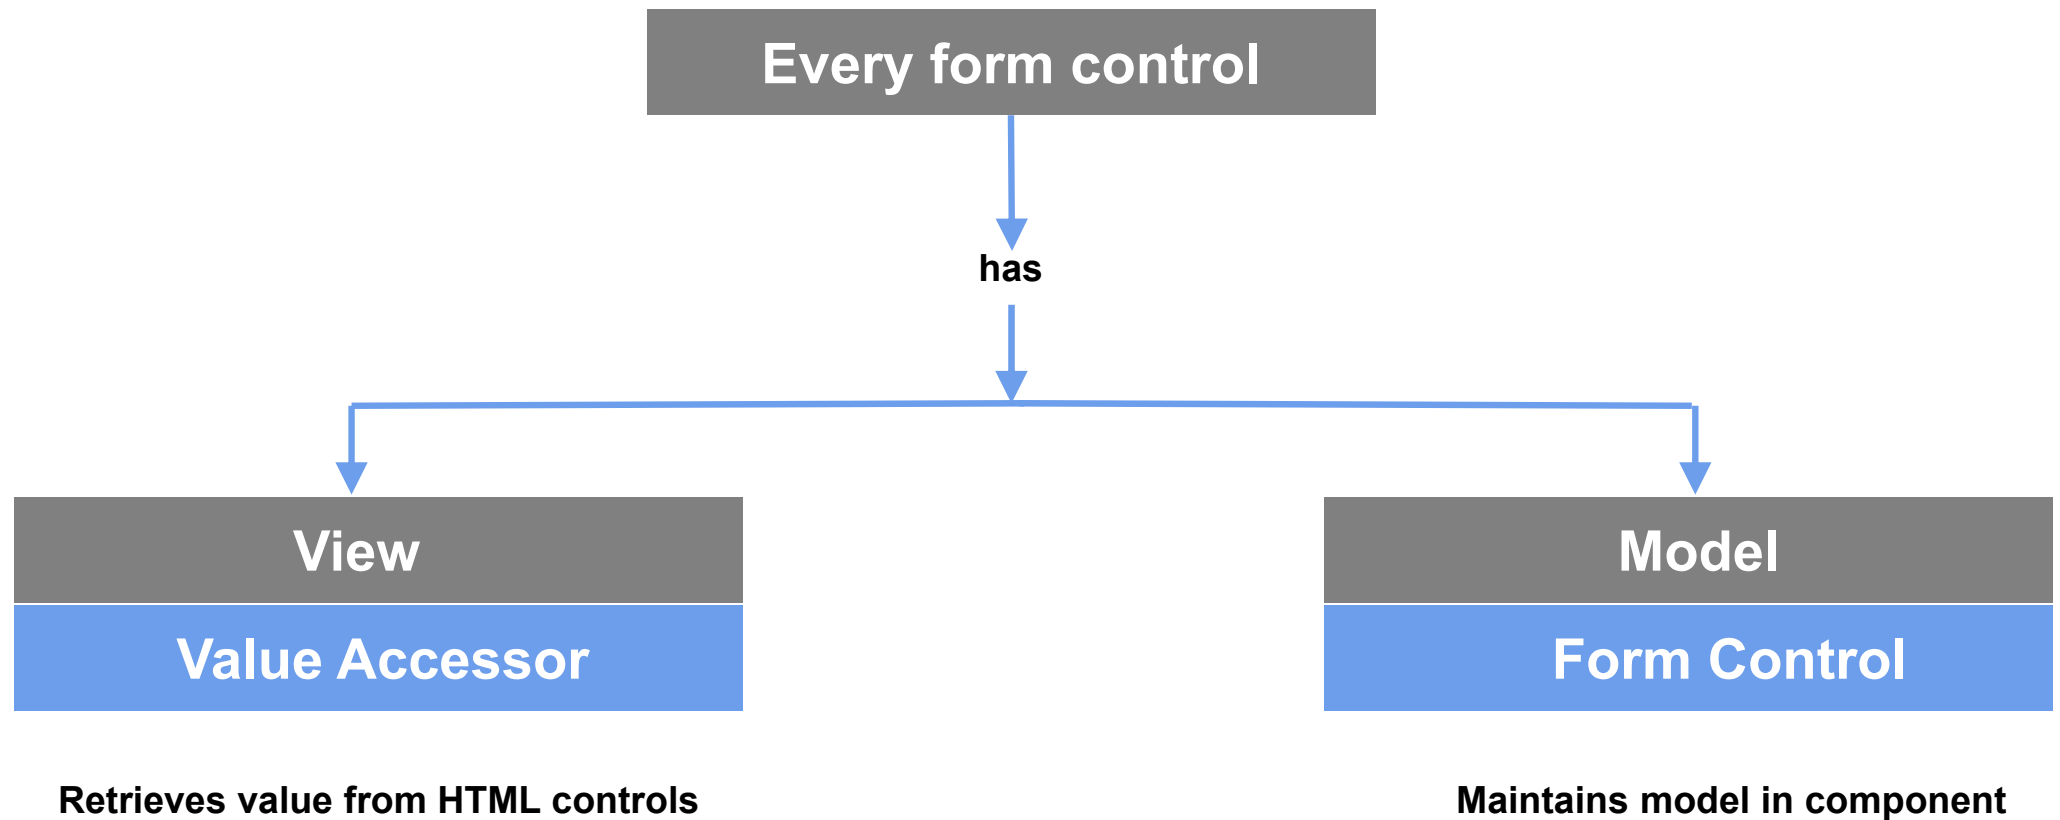

## Template Driven Forms

- Source of truth is the Template
- Define templates. Angular generates form model o/t fly
- Less descriptive
- Quickly Build simple forms – Less control
- Less testable

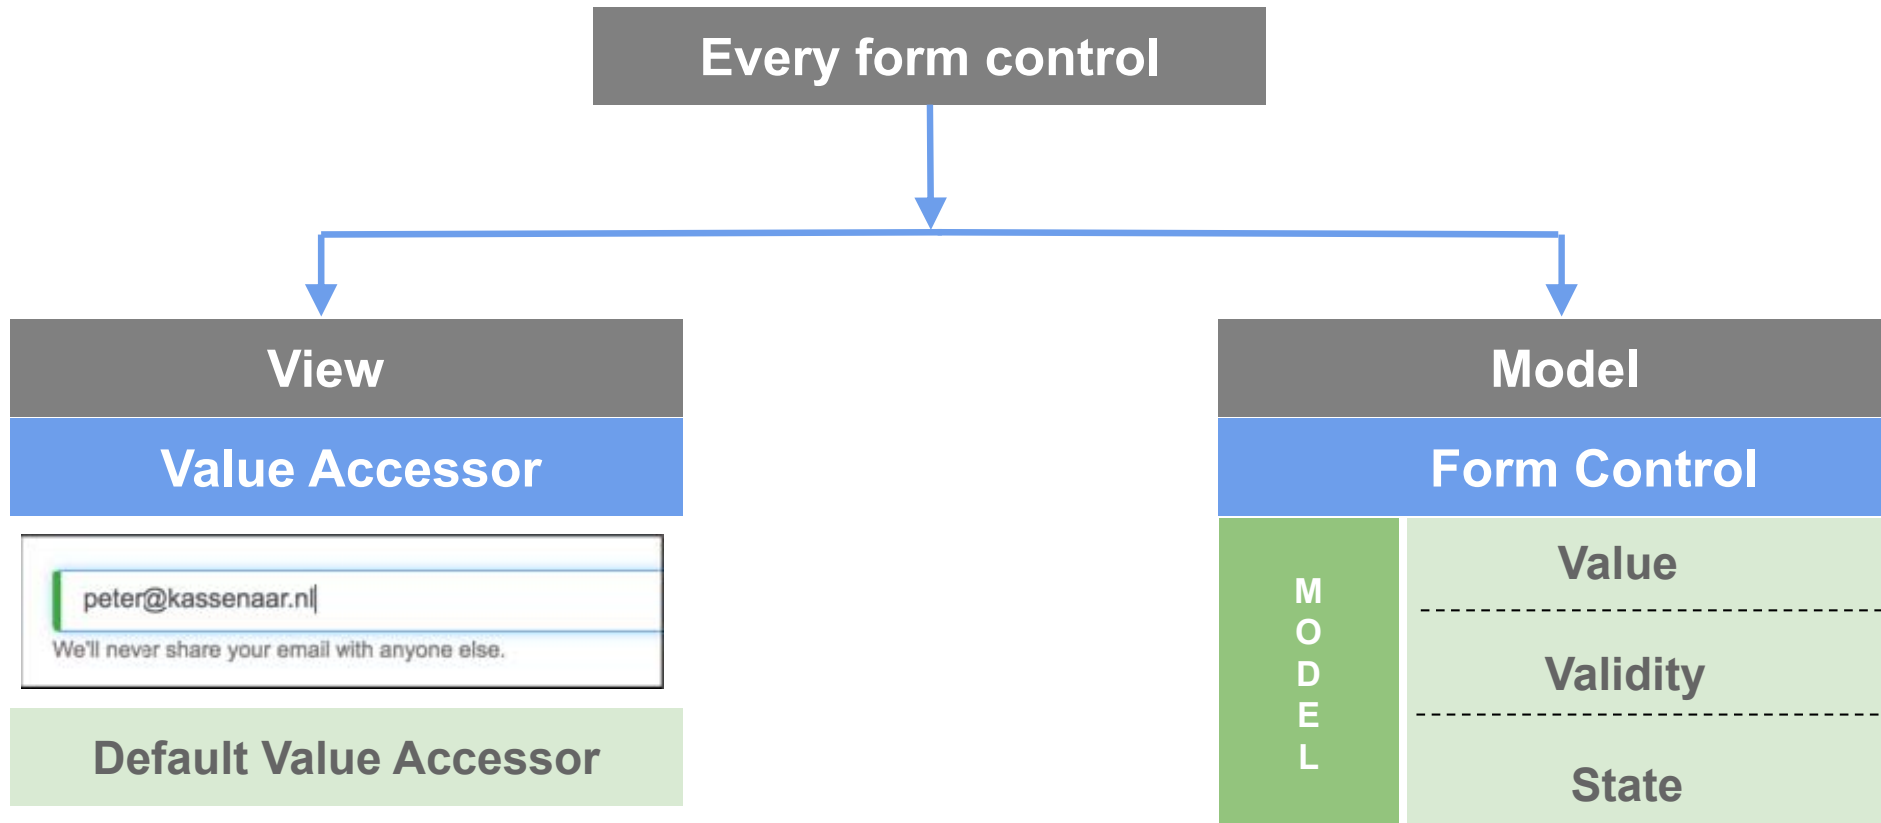

## Model Driven (Reactive Forms)

- Source of truth is the component class / directive
- Instantiate Form model and Control model yourself
- More Descriptive
- Code all the details. Takes more time, gives more control
- Very good testable

# Angular 2 Forms - Fundamentals

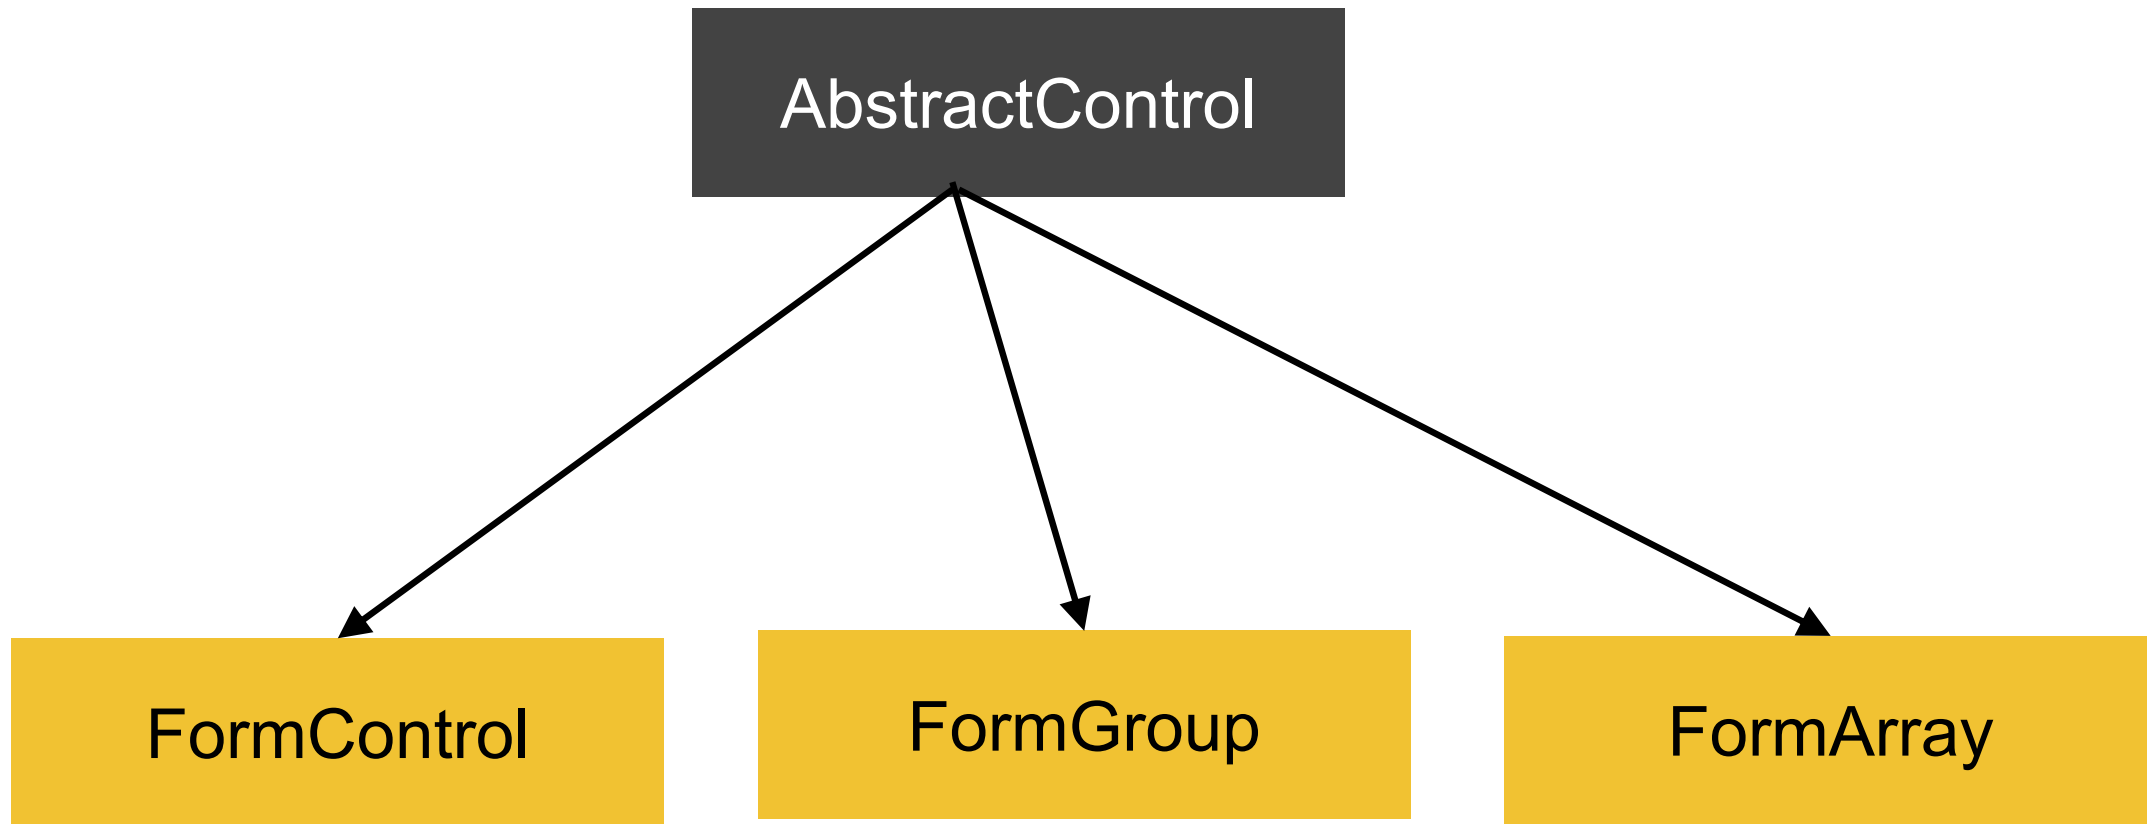

# In more detail

# Angular 2 Forms - Base class

```
export abstract class AbstractControl {  
    _value: any;  
  
    ...  
  
    private _status: string;  
    private _errors: {[key: string]: any};  
    private _pristine: boolean = true;  
    private _touched: boolean = false;  
  
    ...  
  
    get value(): any { return this._value; }  
    get valid(): boolean { return this._status === VALID; }  
  
    ...  
  
    abstract setValue(value: any, options?: Object): void;  
  
    ...  
}
```

# Angular 2 Forms – extended classes

# Control classes in code

```
653 export class FormControl extends AbstractControl {
654   /** @internal */
655   _onChange: Function[] = [];
656
657   constructor(
658     854 export class FormGroup extends AbstractControl {
659     855   constructor(
660     856     public controls: {[key: string]: AbstractControl}, validator: ValidatorFn = null,
661     857     asyncValidator: AsyncValidatorFn = null) {
662     858   super(validator, asyncValidator);
663     859   this._initObservables();
664     860   t
665     861   t
666     862   }
667     863   }
668     1155 export class FormArray extends AbstractControl {
669     1156   constructor(
670     1157     public controls: AbstractControl[], validator: ValidatorFn = null,
671     1158     asyncValidator: AsyncValidatorFn = null) {
672     1159   super(validator, asyncValidator);
673     1160   this._initObservables();
674     1161   this._setUpControls();
675     1162   this.updateValueAndValidity({onlySelf: true, emitEvent: false});
676     1163   }
```

<https://github.com/angular/angular/blob/master/modules/%40angular/forms/src/model.ts>

# Summary – what have we learned so far

**1**

**Template Driven Forms**

Less to code

**2**

**Model Driven Forms**

More to code

**3**

**Model**

Abstract Control,  
FormControl/Group/Array

# Angular 2 – Types of Forms

**Template Driven Forms**

Model Driven  
(Reactive Forms)

# Let's build a template driven form!

- Step 1 – Add (or check) `FormsModule` in `app/main.ts`

```
import {platformBrowserDynamic} from '@angular/platform-browser-dynamic';
```

```
import {FormsModule} from '@angular/forms';
```

```
import {AppModule} from './app.module';
```

## Step 2 – Add FormsModule to app.module.ts

```
import {NgModule}      from '@angular/core';  
import {BrowserModule} from '@angular/platform-browser';  
import {FormsModule}   from '@angular/forms';
```

```
import {AppComponent} from './app.component';
```

```
@NgModule({  
  imports      : [BrowserModule, FormsModule],  
  declarations : [AppComponent],  
  bootstrap    : [AppComponent]  
})  
  
export class AppModule {  
}
```

## Step 3 – write form in HTML

```
<form novalidate>
  <div class="form-group">
    <label for="inputEmail">Email address</label>
    <input type="email" class="form-control" id="inputEmail"
      placeholder="Enter email" name="email">
    <small class="form-text text-muted">
      We'll never share your email with anyone else.
    </small>
  </div>
  <div class="form-group">
    <label for="inputPassword">Password</label>
    <input type="password" class="form-control" id="inputPassword"
      placeholder="Password" name="password">
  </div>

  <button type="submit" class="btn btn-primary">Submit</button>
</form>
```

This is just plain HTML. No Angular stuff here...

## Step 4. Defining a Template Driven Form

- Add #myForm="ngForm" to the <form> tag
  - This declares a local variable with the name #myForm to the <form> element. It is of type NgForm
- Add ngModel to each and every form field
  - No value necessary

```
<form novalidate #myForm="ngForm">
  <div class="form-group">
    <input type="email" class="form-control" id="inputEmail"
      placeholder="Enter email" name="email" ngModel>
  </div>
  <div class="form-group">
    <input type="password" class="form-control" ngModel
      id="inputPassword" placeholder="Password" name="password">
  </div>
```

# Just checking – Sample results pane

```
<div class="form-result">
  <h3>Validity</h3>
  <div class="validity" [ngClass]="{'invalid-form': !myForm.valid}">
    <div *ngIf="myForm.valid">Valid</div>
    <div *ngIf="!myForm.valid">Invalid</div>
  </div>
  <h3>Results</h3>
  <div class="result">
    {{ myForm.value | json }}
  </div>
</div>
```

Just to show runtime results of the Validity and Value of the form using

myForm.valid

myForm.value

# Results so far

## 17a - Angular 2 - Template Driven Forms

**Email address**

We'll never share your email with anyone else.

**Password**

Validity

Valid

Results

```
{ "email": "", "password": "" }
```

# Checkpoint

- The `#myForm` exposes the value and the validity of the form as a whole.
- `ngModel` adds the individual controls to the `#myForm`.
- You can now check it's value and state in the results pane
- Try what happens if you remove one of the `ngModel` directives!
- Check for yourself: the value of a form is a JSON-object.

# Addressing individual controls

# Retrieve values from individual controls

- Do the same as with the form
- Add for example #email="ngModel" to input field
- Now, the value, validity and state (i.e. its ValueAccessors!) are accessible through the local template variable

```
<label for="inputEmail">Email address</label>
```

```
<pre>value: {{ email.value }} - valid : {{ email.valid}}</pre>
```

```
<input type="email" class="form-control" id="inputEmail"  
      placeholder="Enter email" name="email" ngModel #email="ngModel">
```

```
<small class="form-text text-muted">
```

```
  We'll never share your email with anyone else.
```

```
</small>
```

# Required fields

- Add HTML5 attribute required to the input field.
- No checking on type yet!
  - It's just required.

```
<input type="email" class="form-control" id="inputEmail"  
placeholder="Enter email" name="email" ngModel #email="ngModel" required>
```

## 17a - Template Driven Forms /app.component2.html | .ts

### Email address

value: - valid : false

We'll never share your email with anyone else.

### Password

### Validity

Invalid

### Results

```
{ "email": "", "password": "" }
```

## 17a - Template Driven Forms /app.component2.html | .ts

### Email address

value: test - valid : true

We'll never share your email with anyone else.

### Validity

Valid

### Results

# Using ngModelGroup

# Adding ngModelGroup

- Combining form fields into logical groups

```
<div ngModelGroup="customer" #customer="ngModelGroup">  
  <div class="form-group">  
    ...  
  </div>  
</div>
```

Use a local template variable (i.e. `#customer="ngModelGroup"`) only if you want to have access to the state and validity of the group as a whole.

# ngModelGroup creates a nested object

## 17a - ngModelGroup

/app.component3.html | .ts

---

**Email address**

value: info@kassenaar.com - valid : true

info@kassenaar.com

We'll never share your email with anyone else.

**Password**

value: test - valid : true

....

**Prefix**

Mr.

**First Name**

Peter

**Last Name**

Kassenaar

```
value {  
  "namePrefix": "Mr.",  
  "firstName": "Peter",  
  "lastName": "Kassenaar"  
}  
valid: true
```

**Submit**

Validity

Valid

Results

```
{ "email": "info@kassenaar.com", "password": "test", "customer":  
  { "namePrefix": "Mr.", "firstName": "Peter", "lastName":  
    "Kassenaar" } }
```

# Submitting forms

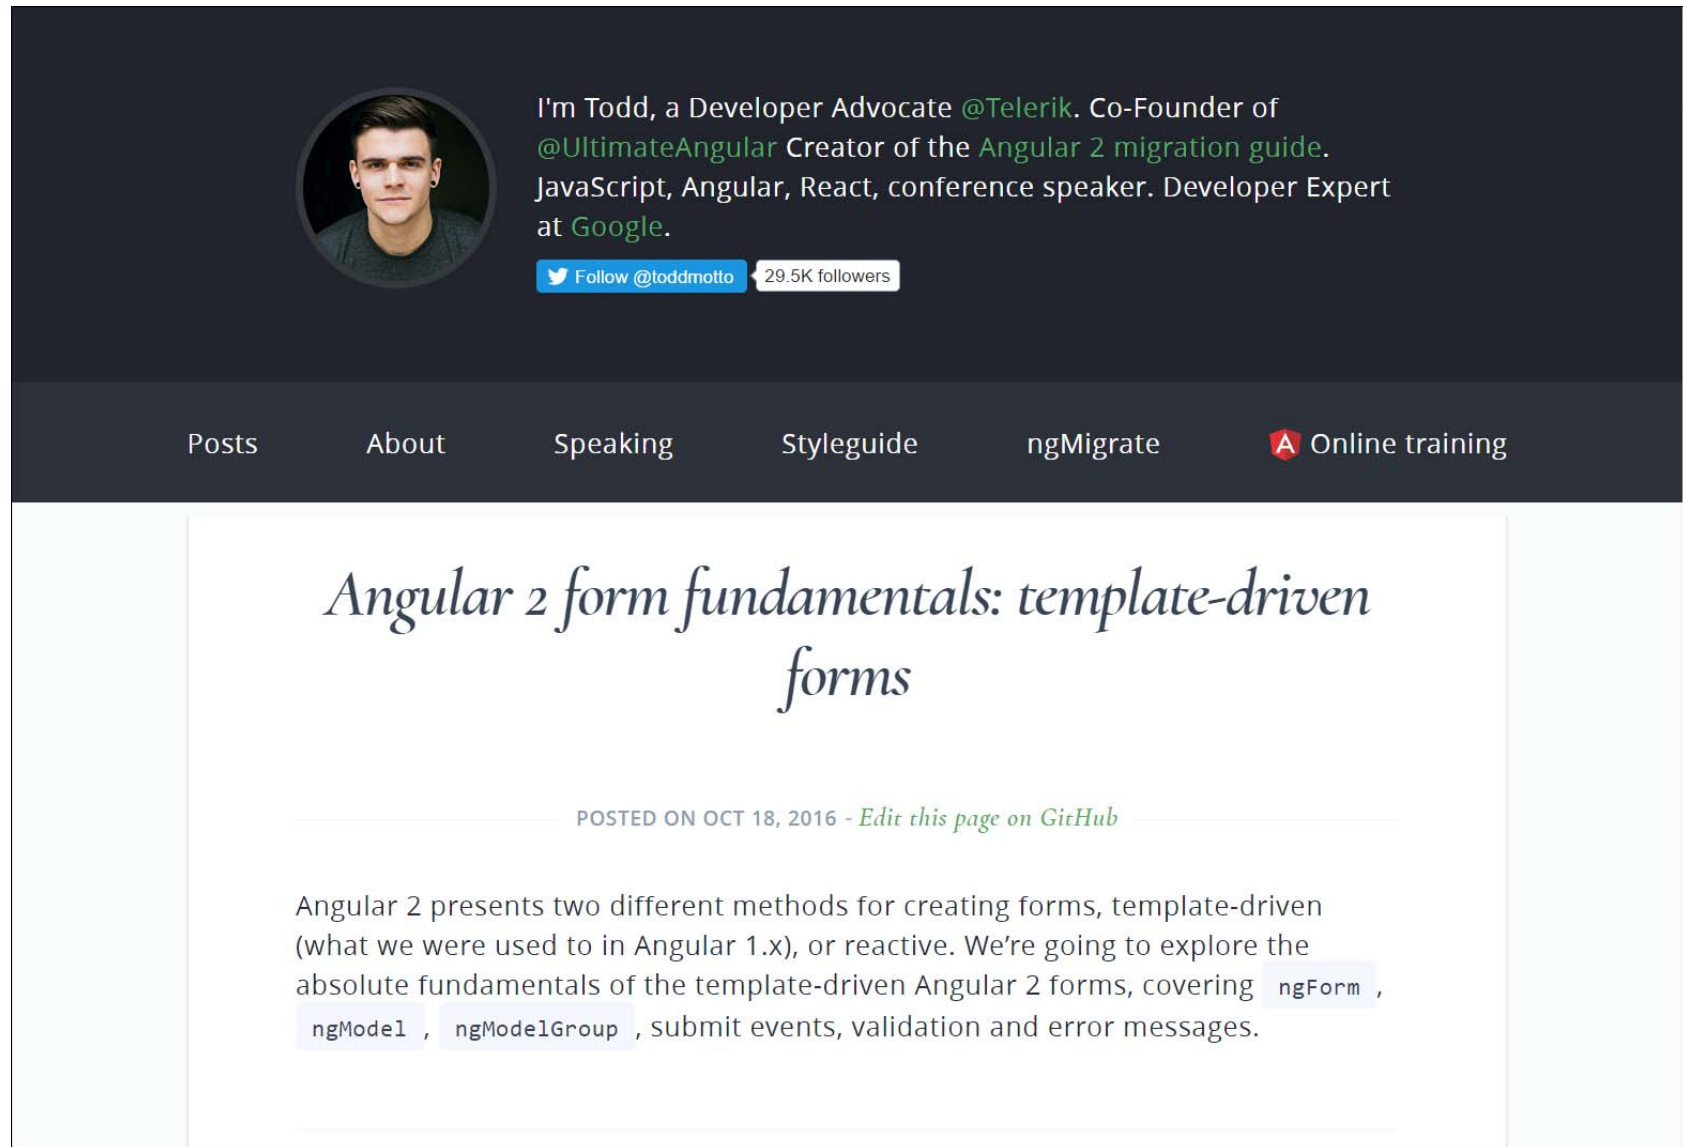

# Define a (click) handler on the button

- Only activate the button if the form is valid
- Pass `myForm` as a parameter
- Note: no actual need for two-way databinding with `[(ngModel)]`

```
<button type="submit" class="btn btn-primary"
        (click)="onSubmit(myForm)"
        [disabled]="!myForm.valid">
  Submit
</button>
```

```
onSubmit(form){
  console.log('Form submitted: ', form.value);
  alert('Form submitted!' + JSON.stringify(form.value))
}
```

## Angular 2 form fundamentals: template-driven forms

POSTED ON OCT 18, 2016 - [Edit this page on GitHub](#)

Angular 2 presents two different methods for creating forms, template-driven (what we were used to in Angular 1.x), or reactive. We're going to explore the absolute fundamentals of the template-driven Angular 2 forms, covering `ngForm`, `ngModel`, `ngModelGroup`, submit events, validation and error messages.

<https://toddmotto.com/angular-2-forms-template-driven>

# Model Driven Forms

Or: *Reactive Forms*

# Reactive Forms

- Based on *reactive programming* we already know
  - Events, Event Emitters
  - Observables
- Every form control is an observable!

```
export abstract class AbstractControl {  
  
    ...  
    private _valueChanges: EventEmitter<any>;  
    ...  
    get valueChanges(): Observable<any> {  
        return this._valueChanges;  
    }  
    ...  
}
```

# Differences - key things to remember

- No more `ngForm` → use `[formGroup]`
- No more `ngModel` → use `formControlName`
- Form state lives in the Component, *not* in the View
- Possible validations are in the Component, not in the View
- The view is *not* generated for you.
- You need to write the HTML yourself

# Form Controls are observables

- Import & instantiate in the Component
- Build your model in `constructor` or `ngOnInit`.
- Listen to changes (`.subscribe()`) and act accordingly:

```
export class AppComponent1 implements OnInit {
```

```
  myReactiveForm: FormGroup;
```

```
  constructor(private FormBuilder: FormBuilder) {  
  }
```

```
  ngOnInit() {
```

```
    this.myReactiveForm = this.formBuilder.group({
```

```
      email    : '',
```

```
      password: ''
```

```
    })
```

```
  }
```

```
}
```

# Subscribe to those observables

// 1. complete form

```
this.myReactiveForm.valueChanges.subscribe((value)=>{  
    console.log(value);  
});
```

// 2. watch just one control

```
this.myReactiveForm.get('email').valueChanges.subscribe((value)=>{  
    console.log(value);  
});
```

# Building reactive forms

# Step 1 – import ReactiveFormsModule

- app.module.ts

```
import {NgModule}      from '@angular/core';
import {BrowserModule} from '@angular/platform-browser';
import {FormsModule, ReactiveFormsModule} from '@angular/forms';
import ...

@NgModule({
  imports      : [
    BrowserModule,
    FormsModule,
    ReactiveFormsModule,
    ...
  ],
  ...
})
export class AppModule {
}
```

## Step 2 – use [formGroup] and formControlName

```
<form novalidate [formGroup]="myReactiveForm">  
  <div class="form-group">  
    <label for="inputEmail">Email address</label>  
    <input type="email" class="form-control" id="inputEmail"  
      placeholder="Enter email" name="email"  
      formControlName="email">  
  </div>  
  ...  
  // all other controls  
</form>
```

# Step 3 – Build your form in Component

```
export class AppComponent1 implements OnInit {
  myReactiveForm: FormGroup;
  constructor(private FormBuilder: FormBuilder) {
  }
  ngOnInit() {
    // 1. Define the model of Reactive Form.
    // Notice the nested FormBuilder.group() for group Customer
    this.myReactiveForm = this.FormBuilder.group({
      email    : '',
      password: '',
      customer: this.FormBuilder.group({
        prefix: '',
        firstName: '',
        lastName: ''
      })
    })
  }
}
```

# Subscribe to changes

```
ngOnInit() {
```

```
...
```

```
// 2. Subscribe to changes at form level or...
```

```
this.myReactiveForm.valueChanges.subscribe((value)=>{  
    console.log('Changes at form level: ', value);  
});
```

```
// 3. Subscribe to changes at control level.
```

```
this.myReactiveForm.get('email').valueChanges.subscribe((value)=>{  
    console.log('Changes at control level: ', value);  
});
```

```
}
```

# Submitting a reactive form

- Can be based on `.valueChanges()` (though not very likely) for any given form control or complete form
- Use just `.click()` event handler for submit button

```
<button type="submit" class="btn btn-primary"
      (click)="onSubmit()"
      [disabled]="!myReactiveForm.valid">
  Submit
</button>
```

```
onSubmit() {
  console.log('Form submitted: ', this.myReactiveForm.value);
  // TODO: do something useful with form
}
```

# Form Validation

# 1. Validating Template driven forms

Use HTML5-attributes like `required`, `pattern`, `minlength` and so on.

Under the hood, these are actually Angular directives!

Angular adds/removes corresponding classes.

```
<input type="password" class="form-control" ngModel  
      id="inputPassword" placeholder="Password" name="password"
```

```
#pw="ngModel" required minlength="6">
```

# Validating reactive forms

No more declarative attributes `required`, `minlength`, `maxlength` and so on.

Add `validator` on the component class instead.

Configure validator per your needs.

# Angular 2 built-in validators

[angular/modules/@angular/forms/src/validators.ts](#)

```
export class Validators {  
  
  static required(control: AbstractControl): {[key: string]: boolean} {  
    }  
  
  static minLength(minLength: number): ValidatorFn {  
    }  
  
  static maxLength(maxLength: number): ValidatorFn {  
    }  
  
  static pattern(pattern: string): ValidatorFn {  
    }  
  
  static nullValidator(c: AbstractControl): {  
    }  
  
  . . .  
}
```

# Adding default Validators

- Adding Validators to class definition
  - `email : ['', Validators.required],`
- Multiple validations? Add an array of Validators, using `Validators.compose()`

```
this.myReactiveForm = this.formBuilder.group({  
  email : ['', Validators.required],  
  password: ['', Validators.compose([Validators.required, Validators.minLength(6)])],  
  confirm: ['', Validators.compose([Validators.required, Validators.minLength(6)])],  
  ...  
});
```

# Adding Custom Validators

- Creating a Password-confirm validator
- Steps:
  1. Create a validation function, taking `AbstractControl` as a parameter
  2. Write your logic
  3. Don't forget: pass the function in as a configuration parameter for the group or form you are validating!

```
function passwordMatcher(control: AbstractControl) {  
    return control.get('password').value === control.get('confirm').value  
        ? null : {'nomatch': true};  
  
    // we *could* return just true/false here, but by returning an object  
    // we're more flexible in composing our validators.  
}
```

```
this.myReactiveForm = this.formBuilder.group({  
    email    : ['', Validators.required],  
    password: ['', Validators.compose([Validators.required, Validators.minLength(6)])],  
    confirm  : ['', Validators.compose([Validators.required, Validators.minLength(6)])],  
    },  
    {validator: passwordMatcher} // pass in the validator function  
);
```

# More on FormBuilder class

- <https://angular.io/docs/ts/latest/api/forms/index/FormBuilder-class.html>
- Information on using and configuring FormBuilder

**FormBuilder** STABLE  
CLASS

**What it does**

Creates an `AbstractControl` from a user-specified configuration.

It is essentially syntactic sugar that shortens the `new FormGroup()`, `new FormControl()`, and `new FormArray()` boilerplate that can build up in larger forms.

**How to use**

To use, inject `FormBuilder` into your component class. You can then call its methods directly.

```
1. import {Component, Inject} from '@angular/core';
2. import {FormBuilder, FormGroup, Validators} from '@angular/forms';
3.
4. @Component({
5.   selector: 'example-app',
6.   template: `
```

# Subscribing to form events

Working with Observables (again). Typeahead demo

# Define a form

```
<form novalidate [formGroup]="searchForm">  
  <div class="form-group">  
    <label for="searchYouTube">Search YouTube</label>  
    <input type="text" class="form-control" id="searchYouTube"  
      formControlName="searchYouTube"  
      placeholder="Search YouTube" name="search">  
  </div>  
  
</form>
```

# Define component

- Compose a class, subscribe to `.valueChanges()` event

```
import {Http, Response} from '@angular/http';
import {Observable} from 'rxjs/Observable'
import {FormControl, FormGroup} from "@angular/forms";
...
// import just the operators we need, not import 'rxjs/Rx'
import 'rxjs/add/operator/map';
import 'rxjs/add/operator/switchMap';
import 'rxjs/add/operator/debounceTime';

// define some constants
const BASE_URL = 'https://www.googleapis.com/youtube/v3/search';
const API_KEY = 'AIzaSyBdi3LXzf1xWXOAVgAwNkGvjnM1TwSV4VU';
// compose a url to search for, based on a query/keyword
const makeURL = (query: string) => `${BASE_URL}?q=${query}&part=snippet&key=${API_KEY}`;
```

```

@Component({
  selector    : 'component1',
  templateUrl: 'app/component1/app.component1.html'
})
export class AppComponent1 implements OnInit {
  videos: Observable<any[]>;

  // compose our form
  searchYouTube = new FormControl();
  searchForm    = new FormGroup({
    searchYouTube: this.searchYouTube,
  });

  constructor(private http: Http) {
  }

  ngOnInit() {
    // subscribe to Youtube input textbox and bind async (see html)
    this.videos = this.searchYouTube.valueChanges
      .debounceTime(600)           // wait for 600ms to hit the API
      .map(query => makeURL(query)) // turn keyword into a real youtube-URL
      .switchMap(url => this.http.get(url)) // wait for, and switch to the Observable that my http get call returns (mo
      .map((res: Response) => res.json()) // map its response to json
      .map(response => response.items);  // unwrap the response and return only the items array
  }
}

```

- See 17c as an example
